

**Panel A: Repeat Victimization Frequency
(Inverted-U Non-Monotonicity)**

**Panel B: Attack Density per USD Volume
(Reciprocal of Avg Trade Size)**

Source: Dune Analytics sandwich-detection export, 2024–2025. Sample: Victim-side base (3.75M attack events across 413,129 unique addresses). Notes: Panel A displays mean attacks per unique victim address with 95% Poisson confidence intervals; because victim sample sizes are in the hundreds of thousands ($N \geq 38,606$), Poisson standard errors are extremely small (≤ 0.043), rendering the 95% CI error bars smaller than the plot markers/bar caps. Panel B displays attack density per \$1,000 traded on a logarithmic vertical axis. By mechanical identity, Panel B equals 1,000 divided by average trade size by construction, reflecting the 157.9x Institutional-to-Retail trade size spread.
